Formal Alternatives as a Solution to the Proviso Problem

Raj Singh
Massachusetts Institute of Technology

This paper investigates a particular problem concerning presupposition accommodation. Let $\psi$ and $X$ be sentences, and suppose $\psi$ presupposes $X$. We represent this as $\psi\{X\}$. Suppose the speaker and hearer of a conversation are in context $c$. Suppose further that the speaker wishes to update the context $c$ with the information in $\psi$, an operation we represent as $c[\psi\{X\}]$. $\psi\{X\}$ imposes a requirement on $c$ that has to be met for the update to take place: $c$ already has to entail $X$. In terms of update operations, this means that if we try updating $c$ with $X$, we just get back $c$: $c[X] = c$. When this condition is met, we say that $c$ satisfies $X$, or that $c$ is a fixed point for $[X]$. But what if $c$ is not a fixed point for $[X]$? What happens when the condition is not met?

There are at least two possible outcomes: (i) either communication breaks down, or (ii) we make some repair $[Y]$ to $c$ so that update will be defined after all, i.e. we update $c$ with $Y$, $c[Y]$, so that $c[Y]$ ends up satisfying $X$. Call this repair process accommodation Lewis (1979). We then update the new context resulting from accommodation of $Y$ with $\psi, c[Y][\psi]$. The question I explore in these pages is: Is there anything more to say about this repair process than simply “do something?” By detailed investigation of a particular puzzle in the theory of presupposition accommodation, this paper will: (i) Present empirical evidence that there are formal restrictions on the allowable repairs $[Y]$ that can be made, and (ii) Derive the restricted set of allowable repairs from the instructions encoded in the context-change potentials defined in Heim (1983). We will see that the derivation of the set of alternatives makes crucial reference to the formal descriptions of context-change potentials (context-change potential descriptions, or CCPDs). Thus, the system here agrees with Geurts (1996) that a more syntactic approach to presupposition accommodation seems called for.

For much helpful discussion on the thoughts presented here, I would like to thank Pranav Anand, Asaf Bachrach, Chris Barker, Hiba Bou Akar, Greg Carlson, Emmanuel Chemla, Noam Chomsky, Mike Collins, Cleo Condoravdi, Veneeta Dayal, Ted Gibson, Aravind Joshi, Lauri Karttunen, Ali Mohammad, Jeff Pelletier, Orin Percus, Alejandro Pérez Carballo, Stanley Peters, Chris Potts, Philippe Schlenker, Florian Schwartz, Ken Shan, Benjamin Spector, Luke Zettlemoyer, two anonymous SALT reviewers, and especially Roni Katzir. I was also glad of thoughtful comments and questions from audiences at MIT’s LF Reading Group, Xerox-Parc, the MIT-Paris Workshop on Implicatures and Presupposition at the ENS in Paris, and SALT 17 at the University of Connecticut in Storrs, CT. I am most indebted to: Kai von Fintel, Danny Fox, Irene Heim, and Bob Stalnaker, for their very valuable and dedicated guidance. In a different sort of way, I should thank the Social Sciences and Humanities Research Council of Canada for their support (Number 752-2004-0542), and the MIT-France Seed Fund for Collaborative Research on Presupposition and Implicatures.

1We follow here as closely as possible the notation of Geurts (1996).
1. The Proviso Problem

Consider sentences of the form \( \text{if } \phi, \text{ then } \psi \{ \text{X} \} \). “Satisfaction theories” of presupposition (Karttunen (1974), Stalnaker (1974), Heim (1983), Beaver (2001), von Fintel (2006), among others) predict that the semantic presupposition of this sentence is \( \text{if } \phi, \text{ then } \text{X} \).\(^2\) A rather straightforward proposal concerning accommodation would be the following: when \( c \) does not satisfy the presupposition of \( \text{if } \phi, \text{ then } \text{X} \), i.e. when \( c \) is not a fixed point for [if \( \phi \), then \( \text{X} \)], we repair \( c \) by updating it with the semantic presupposition, and then we update the result with the content of the sentence: \( c[\text{if } \phi, \text{ then } \text{X}][\text{if } \phi, \text{ then } \psi] \). However, Gazdar (1979), van der Sandt (1992) and Geurts (1996, 1999) observe that often times the repair we make is not [if \( \phi \), then \( \text{X} \)], but rather \( \text{X} \) simpliciter:

\[
\begin{align*}
(1) & \quad \text{If John flies to Toronto, his sister will pick him up from the airport} \\
\text{Semantic Presupposition} & \quad \text{If John flies to Toronto, he has a sister} \\
\text{Actual Accommodation} & \quad \text{John has a sister}
\end{align*}
\]

This fact teaches us that we need to supplement satisfaction theories of presupposition with some further theoretical construct, call it \( P \), which, upon being fed a conditional presupposition \( \text{if } \phi, \text{ then } \text{X} \) by the grammar, returns the stronger alternative \( \text{X} \) as the repair that should be made. However, note that conditional presuppositions are not always strengthened in this fashion:

\[
\begin{align*}
(2) & \quad \text{If John is a scuba diver, he’ll bring his wetsuit}\(^3\) \\
\text{Semantic Presupposition} & \quad \text{If John is a scuba diver, he has a wetsuit} \\
\text{Actual Accommodation} & \quad \text{If John is a scuba diver, he has a wetsuit}
\end{align*}
\]

Thus, the output of \( P \) is not deterministic: when the grammar inputs a conditional presupposition, \( P \) will sometimes output the grammar’s input, and will sometimes output something stronger. To complicate matters further, Geurts (1996, 1999) notes that when conditional presuppositions \( \text{if } \phi, \text{ then } \text{X} \) are triggered under factive verbs like know, they are never strengthened to \( \text{X} \):

\[
\begin{align*}
(3) & \quad \text{Mary knows that if John flies to Toronto, he has a sister} \\
\text{Semantic Presupposition} & \quad \text{If John flies to Toronto, he has a sister} \\
\text{Actual Accommodation} & \quad \text{If John flies to Toronto, he has a sister}
\end{align*}
\]

To summarize:

\[
\begin{align*}
(4) & \quad \text{If } \phi, \text{ then } \psi \{ \text{X} \} \\
\text{Semantic Presupposition} & \quad \text{If } \phi, \text{ then } \text{X}
\end{align*}
\]

\(^2\)Other theories that make this prediction include Karttunen and Peters (1979), van Rooij (2007), and Schlenker (2007).

\(^3\)From Geurts (1996).
Accommodation Possibilities \( \{ \text{If } \phi \text{ then } X, X \} \)

(5) \( K_m(\text{If } \phi, \text{ then } X) \)

Semantic Presupposition \( \text{If } \phi, \text{ then } X \)

Accommodation Possibilities \( \{ \text{If } \phi \text{ then } X \} \)

For our purposes, we may state the proviso problem as follows:

The Proviso Problem When the semantics generates conditional presuppositions \( \{ \text{if } \phi, \text{ then } X \} \), is there a characterization of P that can predict when conditional presuppositions can and cannot be strengthened and, when they can, when they will and when they will not be strengthened and, when they will be strengthened, what exactly they will be strengthened to?

I aim in this paper to provide an explicit characterization of P.

2. An Existing Theory of P: Accommodation as Holistic Inference

I am not by any means the first to attempt to provide a solution to the proviso problem. Beaver (2001), von Fintel (2006), and Heim (2006) (henceforth BvFH) represent one prominent line of response from the satisfaction theory camp. The response goes as follows. As a matter of presupposition projection, satisfaction theories correctly predict that conditional sentences \( \{ \text{if } \phi, \text{ then } \psi \} \{ X \} \) and knowledge attribution sentences \( \{ K_m(\text{If } \phi, \text{ then } X) \} \) semantically presuppose \( \{ \text{if } \phi, \text{ then } X \} \). The semantic presupposition is the minimal amount of information that needs to be added to c in order to ensure that update is defined. How does the minimal requirement, generated by the grammar, relate to the actual repair that’s made in the course of communication? That’s not a matter of concern for the grammar. It can only say: “I need such and such information to hold in the common ground.” Common sense/plausibility reasoning will then be responsible for deciding what to accommodate.

In its most general form, such reasoning takes the form: (i) Generate a set of hypotheses \( \mathcal{H} \) for accommodation, (ii) Select a member of \( \mathcal{H} \) according to some criterion. This account needs to tell us two things. First, what is the space of hypotheses? Second, what is the relevant decision criterion? I follow here the treatment of Heim (2006) because it is the most explicit concerning these two components.

Quite generally, \( \mathcal{H} \) will be a set of “salient propositions” containing the semantic presupposition, though the concept of “salience” is left unanalyzed. For both \( \{ \text{if } \phi \text{ then } \psi \} \) and \( \{ K_m(\text{If } \phi, \text{ then } X) \} \), the hypothesis space of salient

---

4Karttunen and Peters (1979), Beaver (2006), Pérez Carballo (2007), and van Rooij (2007) represent other responses. Due to space limitations, I will not have occasion to discuss these approaches in any great detail here.
propositions is stipulated to be $\mathcal{H} = \{ \text{if } \phi \text{ then } X, X \}$. Given this hypothesis space, what is the relevant decision criterion?

BvFH and Beaver and Zeevat (To appear) suggest that the hearer performs some kind of plausibility reasoning in making her decision about what to accommodate. Crucially, this reasoning process does not compare the plausibility of the propositions in $\mathcal{H}$. For note that since “X” asymmetrically entails “if $\phi$ then X” there is no reasonable notion of plausibility according to which the former should come out as more plausible than the latter. As we’ve seen, however, “X” is sometimes the preferred accommodation. von Fintel (2006) and Heim (2006) suggest that the plausibility comparison is not over $\mathcal{H}$, but rather over $\mathcal{H}^* = \{ \Box S(\text{if } \phi \text{ then } X) \land \neg \Box S X, \Box S X \}$, where by “$\Box S Z$” we mean something like ‘the speaker takes it for granted that Z’ (Heim (2006)) or ‘the speaker intends it to be common ground that Z’ (von Fintel (2006)).

Heim (2006) derives $\mathcal{H}^*$ from $\mathcal{H}$ in two steps. First, $\mathcal{H}$ is transformed into $\Box S \mathcal{H} = \{ \Box S p : p \in \mathcal{H} \}$. Second, each member of $\Box S \mathcal{H}$ is exhaustified: $\mathcal{H}^* = \{ \text{exh}(\Box S \mathcal{H})(\Box S p) : \Box S p \in \Box S \mathcal{H} \}$. $\mathcal{H}^*$ is then used to impose an ordering on the members of $\mathcal{H}$: for all $r, s \in \mathcal{H}$: $r > s$ iff $\text{exh}(\Box S \mathcal{H})(r)$ is more plausible than $\text{exh}(\Box S \mathcal{H})(s)$. The decision criterion is then: select the maximal member of $\mathcal{H}$ with respect to the order $>$. Let us work through some examples to get a sense for how this reasoning works. Begin with (1): *If John flies to Toronto, his sister will pick him up from the airport.* $\mathcal{H} = \{ \text{If John flies to Toronto he has a sister, John has a sister} \}$. The hearer then asks herself: which is more plausible, (i) that the speaker takes for granted that John has a sister on the condition that he flies to Toronto, but not unconditionally, or (ii) that John has a sister whether or not he flies to Toronto? Since (ii) is more plausible than (i), the accommodation is that John has a sister.

Let us turn now to example (2): *If John is a scuba diver, he’ll bring his wetsuit.* Here, $\mathcal{H} = \{ \text{If John is a scuba diver he has a wetsuit, John has a wetsuit} \}$. The hearer again asks herself: which is more plausible, (i) that the speaker takes for granted that John has a wetsuit on the condition that he is a scuba diver, but not unconditionally, or (ii) that John has a wetsuit whether or not he’s a scuba diver? In this case (i) is more plausible, so the accommodated proposition is that John has a wetsuit if he’s a scuba diver.

I believe this proposal is essentially correct. However, there is a non-trivial issue it needs to address, namely, the issue of what constraints there are, if any,
on the alternatives that are generated. Why are the hypothesis spaces in (1) and (2) the ones we find? And what is the hypothesis space for (3)? Why don’t we find strengthening there? At least two factors could be behind this lack of strengthening. On the one hand, (1) and (3) may have different hypothesis spaces for accommodation. On the other hand, there may be nothing to say about the hypothesis spaces, with general principles of reasoning dictating that strengthening will not take place in (3) but will in (1). 7 Without constraints on \( \mathcal{H} \) there is no way to predict, for any given sentence, what the space of possible repairs is. In principle, \( \mathcal{H} \) could be anything. It is because no substantive constraints are imposed on \( \mathcal{H} \) that I label this approach to accommodation a form of “holistic inference.” Thus, the accommodation system outlined above is fully explicit only once a hypothesis space is stipulated.

This paper has two goals: (i) to argue that the entire process of presupposition accommodation should be formalized, and (ii) to provide an algorithm that generates hypothesis spaces, thereby mechanizing the BvFH account. The argument proceeds in three steps. I begin by providing empirical evidence that not all logically possible strengthenings of the semantic presupposition are available for accommodation. Second, I use this evidence to argue that the restrictions on the hypothesis space must be formal in nature. I then provide a procedure that uses the CCPD of a sentence \( S \) to generate its hypothesis space \( \mathcal{H} \). Since the only information used by the procedure is the syntax of \( S \)'s CCP, the set of alternatives is context-invariant. It is for this reason that I call the alternatives formal alternatives. This set of alternatives \( \mathcal{H} \) can then be plugged into the BvFH accommodation system to make predictions about what will and will not get accommodated. Thus, this paper is all about clarifying the makeup of the hypothesis space \( \mathcal{H} \).

Before filling in the details, let me sketch the rough form of the solution I offer to the problem defined by the data in (1)-(3). For sentences of the form \( \gamma \text{if } \phi, \theta(X) \gamma \), my procedure will output \( \mathcal{H} = \{ \text{if } \phi \text{ then } X, X \} \). For knowledge-attribution sentences \( \gamma K_{\phi}(\text{If } \phi, \theta(X)) \gamma \) the procedure will generate \( \mathcal{H} = \{ \text{if } \phi \text{ then } X \} \). It therefore follows from the procedure I develop here that the reason you don’t find strengthening under know is that the strengthened alternative is just not generated, i.e. it’s not really an alternative.

---

7 All the responses from satisfaction theorists have taken the latter approach: Beaver (2006) argues that (1) and (3) come with different relevance presuppositions, Heim (2006) argues that they have different implicatures, Pérez Carballo (2007) and van Rooij (2007) argue that (3) makes the beliefs of the subject of the knowledge ascription relevant, which is enough to block default assumptions needed to generate strengthening.

8 These are to be construed as sentences now.
3. A Revised Theory of $P$: On the Modularity of Accommodation

3.1. The Need for a Modular Theory of Accommodation: Restricted Alternatives

One learns a fair amount of information from a sentence. In general, we can visualize the flow of information generated by the utterance of sentence $\gamma \psi \{X\}^\gamma$ in context $c$ as the following update sequence: $c[Y][\psi][Z_1]...[Z_k]$, where $Y$ is what has been accommodated, and the $Z_i$ are further inferences. Given the many inferences drawn from a sentence, how does one probe with any generality that part of the update corresponding to presupposition accommodation?

von Fintel (2004b,c) has argued that there is a test, which he calls the **Hey Wait a Minute Test**, that can serve as a test for distinguishing presupposition and assertion. I argue that the HW AMT can be used to help us characterize the hypothesis space for accommodation:

**The Hey Wait a Minute Test** In response to the speaker’s utterance $\gamma \psi \{X\}^\gamma$ in a context $c$ not satisfying $X$, iff $Y$ is what is to be accommodated, $c[Y][\psi]$, the hearer may object **Hey wait a minute! I didn’t know $Y$!**

Here are some examples of the HWAMT in action:

(6) S: John’s sister will pick him up from the airport.
H: Hey wait a minute! I didn’t know John has a sister!

(7) S: If John flies to Toronto, his sister will pick him up from the airport.
H: Hey wait a minute! I didn’t know John has a sister!

This last example is especially important because it teaches us that the HWAMT probes not only the minimal repair, but rather whatever it is that is supposed to be accommodated.

We now employ the HWAMT to argue that plausibility reasoning over an unrestricted search space cannot be responsible for the accommodation patterns we find. Let’s assume that accommodation *is* governed by plausibility reasoning over an unrestricted search space.

(8) S: Since John was once president of the United States, his daughter must have gone to Yale or Harvard.

**Minimal Repair** $X = \text{John has a daughter}$

**Alternative Repairs** $\{ A = \text{John has a daughter and she is white}, B = \text{John has a daughter and she is black}, C = \text{John has a daughter and she is Latina}, D = \text{John has a daughter and she is Native American}, ... \}$

---

9 We adopt here the idea from Stalnaker (1998) and von Fintel (2006) that there are timing principles governing accommodation, in that it happens after the sentence has been uttered but before update with its content had had a chance to take place.

10 I put aside here the idea that $H$ is constrained by salience, since it is not clear to me what does and does not constitute a salient enough possibility to be considered for membership in $H$. 

□₈A is certainly more plausible than □₈X ∧ ¬□₈A given what we know about the political history of the United States, genetic transmission of information, etc. As such, according to the BvFH account, the first of the following update sequences should be preferred.¹¹

(9) Update Sequence 1: c[A][S]

(10) Update Sequence 2: c[X][S]

Under the HWAMT, contra BvFH’s prediction, it seems only X can go in for accommodation, not the more plausible A:

(11) #Hey wait a minute! I didn’t know John has a white daughter!

(12) Hey wait a minute! I didn’t know John has a daughter!

The HWAMT indicates that what gets accommodated is not the more plausible information that John has a white daughter, but rather the information that John has a daughter, with no indication of what her race might be. Whatever the nature of the inference to John’s daughter being white, the HWAMT teaches us that it has nothing to do with presupposition accommodation. More schematically, that inference would be one of the Zᵢ in our update video c[Y][ψ][Z₁]…[Zₖ], and not Y.

Here is another, perhaps less controversial example:

Context: John’s family has a long history of breeding German Shepherds (and only German Shepherds). Consider it common ground that any member of the family need not have a dog, but if they do, it must be a German Shepherd. Thus, John’s having a dog is contextually equivalent to his having a German Shepherd. John’s friend, Bill, pays a surprise visit to his place. John’s cousin, Mary, answers:

(13) Bill: Hi Mary. Is John home?
Mary: Um, no, he’s out walking his dog.

Now consider the following update sequences:

(14) Update Sequence 1: c[John has a German Shepherd][John is out walking his dog]

(15) Update Sequence 2: c[John has a dog][John is out walking his dog]

¹¹It is clearer that this should be so when reasoning about speaker belief than when reasoning about target common grounds as von Fintel (2006) has proposed.
Note that in this case, since having a dog and having a German Shepherd are contextually equivalent, the target common grounds are identical. As such, under the BvFH system, the HW AMT should be equally (in)felicitous under both update sequences. However, this prediction is not borne out:

(16) #Hey wait a minute! I didn’t know John has a German Shepherd!

(17) Hey wait a minute! I didn’t know John has a dog!

This example teaches us even more strikingly than the previous one that what can go in for \( Y \) is formally restricted. In this example, even though \( c[\text{John has a dog}] = c[\text{John has a German Shepherd}] \), the HWAMT shows us that only the former update sequence is allowed. The accidental contextual equivalence seems to be irrelevant for the accommodation system. We take such facts to indicate that, contra BvFH, presupposition accommodation is not governed by plausibility reasoning over an unrestricted search space.\(^{12}\) In the next section I will state some generalizations about the ways in which the hypothesis spaces for atomic and conditional sentences are restricted. I will expand the discussion to other sentences once I show (in Section 3.3) how these generalizations can be derived from CCPDs.

3.2. Generalizations About Hypothesis Spaces for Accommodation: Atomic and Conditional Sentences

The HWAMT above indicates that in atomic sentences the only allowable repair is the lexically encoded presupposition of the sentence itself:

**Hypothesis Space: Atomic Case** When updating \( c[Y][\psi \{X\}] \), the hypothesis space for accommodation is \( \mathcal{H}' = \{X\} \), i.e. the only value \( Y \) can take is \( Y = X \).

The case of conditionals \( \lceil \text{if } \phi_1 \text{ and } \ldots \text{ and } \phi_k \text{, then } \psi \{X\} \rceil \) is slightly more complicated, as we’ve already seen, for in conditionals there is variability in the allowable repairs. For instance, we’ve seen that when \( k = 1 \), the hypothesis space seems to be: \( \{\text{If } \phi \text{ then } X, X\} \). This suggests the following generalization: The hypothesis space for accommodation in conditional sentences is composed of the semantic presupposition of the conditional plus the presupposition of its consequent. Unfortunately, the proposal doesn’t quite work, as the following example due to Geurts (1996) shows:

(18) If John is a scuba diver and wants to impress his girlfriend, he’ll bring his wetsuit

\(^{12}\)I should mention that several people (Noam Chomsky, Kai von Fintel, Irene Heim, Roni Katzir, and an anonymous SALT reviewer) have pointed out examples of felicitous uses of the HWAMT which do not seem to probe information represented by a formal alternative. I believe I have a response to the counter-examples, but space limitations prevent me from engaging in further discussion here.
The hypothesis space according to this proposal would be: \{If John is a scuba diver and wants to impress his girlfriend he has a wetsuit, John has a wetsuit\}. However, as Geurts (1996) points out, we accommodate from (20) the information that if John is a scuba diver, he has a wetsuit. This corresponds to no element of the hypothesis space.\(^{13}\) It seems we need to get “inside” the conditional. In this case, we need at least If John is a scuba diver, he has a wetsuit to be an alternative. This suggests that in conditional sentences, the hypothesis space is composed of all Left-Strengthenings of the minimal repair:

**Hypothesis Space: Conditionals** When updating \(c[Y] if \phi_1 and \ldots and \phi_k, then \psi\{X\}\), the hypothesis space for accommodation is all Left-Strengthenings of the semantic presupposition: \(H = \{if \phi_1 and \ldots and \phi_k then X, if \phi_1 and \ldots and \phi_{k-1} then X, \ldots, if \phi_2 and \ldots and \phi_k then X, \ldots, if \phi_k then X, X\}\).

For instance, the hypothesis space corresponding to \(\neg if \phi_1 and \phi_2, then \psi\{X\}\) is \(H = \{if \phi_1 and \phi_2 then X, if \phi_1 then X, if \phi_2 then X, X\}\).

### 3.3. Deriving Search Spaces: Local Satisfaction and the Syntax of CCPs

I arrived at the above generalizations through use of the HW AMT and intuitions about the information conveyed by the relevant sentences. However, I haven’t as yet offered a predictive theory. What I have said so far will not be able to tell us, for any given sentence, what its set of alternatives for accommodation should be. This section is devoted to showing that the instructions encoded in CCPs are exactly what is needed to put a predictive theory in place.

There are two important technical notions we need, the notion of a local context and the notion of local satisfaction. Suppose that we wish to execute the CCP of a complex sentence \(S\) on a context \(c\). Suppose that \(\psi\) occurs in an embedded position somewhere in \(S\). Since complex sentences come with complex CCPs, we will find that \([\psi]\) will be executed on a context \(c^*\) which is derived from \(c\) by application of \([\phi_i]\) for zero or more \(\phi_i\). Thus, the context on which \([\psi]\) will be executed will be a (not-necessarily proper) subset of \(c\).

**Definition 1 (Local Contexts)** *Let \(S\) be a sentence uttered in context \(c\), and let \(\psi\) be a sentence embedded in \(S\). The local context for \(\psi\) embedded in \(S\) uttered in context \(c\), \(L(\psi, S, c)\), is that subset of \(c\), \(c^*\), on which \([\psi]\) will be executed, as defined by the CCP of \(S\).*

For instance, consider the case of atomic, negated, conjunctive, and conditional sentences \(S\) uttered in context \(c\):

---

\(^{13}\)Irene Heim (p.c.) raised the question of how we know that this is indeed the accommodation and not, say, the minimal repair itself. My response is: If we accept this sentence at time \(t\), and at some later time \(t’\) come to learn that John doesn’t have a wetsuit, what other information, if any, do we give up? We conclude that John is not a scuba diver, not that John either is not a scuba diver or doesn’t want to impress his girlfriend.
The second important technical concept is that of local satisfaction. Recall that for atomic $\psi \{X\}$, $[\psi \{X\}]$ is defined on $c$ only if $c$ satisfies $X$, i.e. only if $c$ is a fixed point for $[X]$, i.e. only if $c[X] = c$. The satisfaction theory simply extends this to all embedded sentences:

**Definition 2 (Constraint Requiring Local Satisfaction)** Let $S$ be a sentence uttered in context $c$, and let $\psi \{X\}$ be embedded in $S$. Then $\mathcal{L}(\psi \{X\}, S, c)$ must satisfy $X$.

Now suppose we want to update a context $c$ with a sentence $S$, where $S$ is one of (19)-(23). What we want to know is, what does $c$ have to satisfy in order for $c[S]$ to be defined? Or, put another way, if accommodation needs to be made, $c[Y][S]$, what values can $Y$ take on? Can this information be predicted from the Constraint Requiring Local Satisfaction?

Given the CCPs of (19)-(23) and the local satisfaction requirement, certain constraints on $c$ do follow. In (19) and (20) $c$ must satisfy $X$ (this can be read off from the above). In (21) and (22), from the fact that $c'$ needs to satisfy $X$, it is a simple matter to prove that $c$ needs to satisfy $\neg \phi$, then $X \neg$. In (23) one can show that $c$ must satisfy $\neg \phi$ and $\phi \neg$, then $X \neg$. But these are just the minimal requirements imposed on $c$, and so we are just back to the proviso problem. How do these minimal requirements relate to what is actually accommodated? We promised earlier that the space of accommodation possibilities would follow from the instructions encoded in CCPs. Does it?

To make good on our promise, we should be able to take a CCP, and the local satisfaction requirement, and derive the accommodation hypothesis space. Let us pair below the local contexts (that need to satisfy $X$) and the hypothesis space for accommodation (given our generalizations in Section 3.2) for each of (19)-(23) to see if this goal can be met:

19. Hypothesis Space = $\{X\}$; $\mathcal{L}(\psi \{X\}, S, c) = c$
20. Hypothesis Space = \{X\}; \mathcal{L}(\psi\{X\},S,c) = c

21. Hypothesis Space\textsuperscript{14} = \{if \phi then X, X\}; \mathcal{L}(\psi\{X\},S,c) = c'

22. Hypothesis Space = \{if \phi then X, X\}; \mathcal{L}(\psi\{X\},S,c) = c'

23. Hypothesis Space = \{if \phi_1 and \phi_2 then X, if \phi_1 then X, if \phi_2 then X, X\}; \\
\mathcal{L}(\psi\{X\},S,c) = c''

In (19) and (20), the local context is \(c\), so we can tell just by inspection that \(c\) must satisfy \(X\). But why stop there? Why not enlarge the set of alternatives to include more possibilities than just \(X\)? Nothing we’ve said so far rules out this possibility. In (21)-(23), \(c'\) and \(c''\) are just propositions, sets of worlds. Why should they correspond in any systematic way to the hypothesis spaces they correspond to? There just does not seem to be enough information in propositions to recover the hypothesis spaces I’ve paired them with above. The satisfaction theory framework, in its bare essentials, does not provide enough resources to help here. However, we will see that allowing the satisfaction theory to exploit an additional informational resource will suffice to derive the generalizations we promised, and will have the additional effect of turning it into a predictive theory of accommodation.

What is this resource? If we make the assumption that we are granted access not just to what the local context is (as a proposition), but to the instruction encoded in the CCP that tells you how you got from \(c\) to \(c'\), in this case by the application of \([\phi]\) to \(c\), that is all we will need to generate the required hypothesis spaces. First, let us modify our definition of local contexts:\textsuperscript{15}

**Definition 3 (Local Contexts, Revised Version)** The local context for \(\psi\) embedded in \(S\) uttered in context \(c\), \(\mathcal{L}(\psi,S,c)\), is a description \(c[\phi_1]...[\phi_k], k \geq 0\), where the CCP of \(S\) specifies the instruction \(c[\phi_1]...[\phi_k][\psi\{X\}]\).

Let us return now to our pairing of hypothesis spaces and local contexts:

19. Hypothesis Space = \{X\}; \mathcal{L}(\psi\{X\},S,c) = c

\textsuperscript{14}We haven’t discussed the case of conjunctions yet, but this hypothesis space will follow from the procedure we develop in this section.

\textsuperscript{15}We follow Geurts (1996) and focus our attention on local contexts with the syntax \(c[\phi_1]...[\phi_k]\). It should be pointed out, contra Geurts (1996), that this shape of local contexts is not the general case. Relevant counter-examples are \((not \phi) and \psi\{X\})^\top (Danny Fox, p.c.) and \((if (\alpha or \beta), then \psi\{X\})^\top (Jeff Pelletier, p.c.). We provide a more general, recursive definition of local contexts in the Appendix. The procedure for generating hypothesis spaces, developed immediately below, also receives a natural extension. I omit details here.
20. Hypothesis Space = \{X\}; \mathcal{L}(\psi\{X\}, S, c) = c

21. Hypothesis Space = \{if \phi then X, X\}; \mathcal{L}(\psi\{X\}, S, c) = c[\phi]

22. Hypothesis Space = \{if \phi then X, X\}; \mathcal{L}(\psi\{X\}, S, c) = c[\phi]

23. Hypothesis Space = \{if \phi_1 and \phi_2 then X, if \phi_1 then X, if \phi_2 then X, X\}; 
\mathcal{L}(\psi\{X\}, S, c) = c[\phi_1][\phi_2]

**Procedure for Deriving Hypothesis Spaces from CCPDs** Suppose that complex sentence $S$ contains embedded in it sentence $\psi\{X\}$, and that $S$ is uttered in context $c$. Suppose further that $\mathcal{L}(\psi\{X\}, S, c) = c[\phi_1]...[\phi_k]$, where $k \geq 0$. Then the hypothesis space for accommodation (into $c$) is: \{if $\phi_1$ and ... and $\phi_k$ then $X$, if $\phi_1$ and ... and $\phi_{k-1}$ then $X$, ..., if $\phi_2$ and ... and $\phi_k$ then $X$, ..., if $\phi_k$ then $X, X\}.

When $\mathcal{L}(\psi\{X\}, S, c) = c$, the hypothesis space $\mathcal{H}$ is the singleton set $\{X\}$. When $\mathcal{L}(\psi\{X\}, S, c) = c[\phi]$, such as in sentences of the form $\text{if } \phi \text{ then } \psi\{X\}\text{,}$ $\mathcal{H} = \{\text{if } \phi \text{ then } X, X\}$. When we have a sentence like (20), of the form $\text{if } \phi_1 \text{ and } \phi_2 \text{ then } \psi\{X\}$, $\mathcal{L}(\psi\{X\}, S, c) = c[\phi_1][\phi_2]$, so $\mathcal{H} = \{\text{if } \phi_1 \text{ and } \phi_2 \text{ then } X, \text{ if } \phi_1 \text{ then } X, \text{ if } \phi_2 \text{ then } X, X\}$. In general, the size of the hypothesis space corresponding to $\mathcal{L}(\psi\{X\}, S, c) = c[\phi_1]...[\phi_k]$ is $2^k$, so that strengthening is only an option when $k > 0$.

It is important to note, following Geurts (1996), that “the proviso problem isn’t a problem about conditionals - it is also a problem about conditionals.”\textsuperscript{16} The satisfaction theory predicts that conjunctions $\neg\phi$ and $\psi\{X\}$ also generate conditional presuppositions $\text{if } \phi \text{ then } X$. However, as pointed out by Geurts, we come away from such sentences inferring something stronger, viz. $X$. Consider the following example:

(24) John works for Morgan Stanley and his limo is parked outside.

We infer $X = \text{John has a limo}$ from this sentence. This fact is actually consistent with a conditional presupposition. Assuming that $\text{if John works for Morgan Stanley he has a limo}$ is generated as the presupposition of (24), John’s having a limo can be inferred by modus ponens from this conditional presupposition together with the first conjunct $\text{John works for Morgan Stanley}$. The inference to John’s having a limo can also be explained by generating $X$ itself as (24)’s presupposition. My system predicts exactly these alternative possibilities for accommodation: \{if $\phi$ then $X, X\}$. How then can we show that both members of the hypothesis space are

\textsuperscript{16}p.269, emphasis in original.
indeed accommodation possibilities, given that we have an independent explanation for the inference to \(X\) under each?

When we embed (24) under negation, which I predict to be a hole for presupposition (in that \(\neg\phi\) presumes whatever \(\phi\) presupposes), we find that the conditional presupposition *if John works for Morgan Stanley he has a limo* is indeed available:

(25) It’s not the case that (John works for Morgan Stanley and his limo is parked outside).

However, there is no story to be had here tying conditional presuppositions to negated conjunctions, for we accommodate simply that John has a limo in (26):

(26) It’s not the case that (it’s sunny in Cambridge and John’s limo is parked outside).

Thus, like conditionals \(\text{if } \phi, \text{ then } \{X\}\) \(\text{if } \phi, \text{ then } \{X\}\), we see that both members of the predicted search space, \(\{\text{if } \phi \text{ then } X, X\}\), are possible repairs.

It is important to note that, although conjunctions and conditionals differ syntactically and semantically in important ways, they share a crucial feature in the syntax of their CCPs, namely, the descriptions of certain local contexts upon which are imposed constraints of local satisfaction. Such an equivalence is hardly obvious from basic assumptions about the syntax or (static) semantics of these constructions, but they follow naturally once CCPDs are taken seriously.

My proposal actually makes this a more general phenomenon. It will be quite difficult to make generalizations about accommodation based on purely syntactic/semantic properties of sentences unless they bear on the CCPD of the sentence. Sometimes, as in the case of conditionals and conjunctions, constructions with no obvious syntactic or semantic similarities, I predict that they will share the same accommodation possibilities. Other times, I predict that truth-conditionally equivalent sentences should converge in their accommodation possibilities.\(^{17}\) Other times, I predict that truth-conditionally equivalent sentences will differ in accommodation possibilities.\(^{18}\) Again, the only relevant factor governing the space of accommodation possibilities is the CCPD under consideration.

An implicit assumption expressed in the statement of the proviso problem was that if two sentences \(S\) and \(S’\) generate the same presupposition, they should, ceteris paribus, give rise to the same accommodation possibilities. As I hope to have shown here, ceteris are not always paribus. Even if \(S\) and \(S’\) give rise to the same minimal repair, they might nonetheless have CCPDs under which different accommodation possibilities are generated. Thus, although \(\text{if } \phi, \text{ then } \{X\}\) and

---

\(^{17}\)As with \(\text{if } \phi, \text{ and } \phi_2\), then \(\{Y\}\) and \(\text{if } \phi_1, \text{ then if } \phi_2, \text{ then } \{X\}\).

\(^{18}\)If we assume a symmetric or, so that \(c[\phi \text{ or } \psi] = c[\phi] \cup c[\psi]\), and a material implication analysis of conditionals, then \(\text{if } \phi, \text{ or } \{X\}\) is predicted to allow only one accommodation possibility, \(\{X\}\), whereas \(\text{if } \phi, \text{ then } \{X\}\), as we’ve seen, is predicted to allow variability, \(\{\text{if } \phi \text{ then } X, X\}\).
\( \neg K_m(\text{If } \phi, \text{ then } X) \) both generate the same presupposition \( \neg \text{if } \phi \text{ then } X \), under my proposal they could, in principle, exhibit variability in their accommodation behaviour should their CCPDs dictate that this should be so. In the next section I show that this possibility is actually realized.

### 3.4. Embedding Under know

If we wish to know what accommodation possibilities are generated for some construction, the task for us should be clear. We need to write our lexical entries so as to encode the right semantic content and partiality (where applicable). The syntax of CCPs will then tell us what the set of alternatives for accommodation are.

Assuming we had never heard of the proviso problem, what lexical entry would we write for know sentences? We would need to encode: (i) a definedness condition (if applicable), and (ii) its contribution to content. Let us make this our task. How should we proceed?

One robust feature of the interpretation of such sentences is that from \( \neg K_m(\phi) \) one tends to infer that \( \phi \). This factivity inference seems to arise not through standard entailment, but through presupposition, as standard projection tests show:

\[(27) \text{If Mary knows that James Baldwin wrote Notes of a Native Son, she probably has two copies at home} \]

Thus our definedness condition will include a statement like the following:

**Definition 4 (Definedness Condition on Knowledge-Attribution Sentences)**

\[c[K_m(\phi)] \text{ is defined only if } c \text{ satisfies } \phi, \text{ i.e. only if } c[\phi] = c.\]

Note that from this definedness condition follows another, viz. that \( c[\phi] \) must be defined. Thus, if \( \phi \) itself is presuppositional, eg. if \( \phi \) presupposes \( X \), then for \( c[\phi] \) to be defined it must be that \( c \) satisfies \( X \). As a result, \( [K_m(\phi \{X\})] \) will be defined on \( c \) only if (i) \( c \) satisfies \( X \), and (ii) \( c \) satisfies \( \phi \). This is the familiar “hole” property of knowledge attribution sentences. For instance, (28) is predicted to presuppose both that John has a sister, and that John’s sister will pick him up from the airport.

\[(28) \text{Mary knows that John’s sister will pick him up from the airport} \]

Before even writing the content of knowledge attribution sentences, we are in position to say why conditional presuppositions generated under know are never strengthened.\(^{19}\) Consider a sentence like (3) uttered in context \( c \):

\(^{19}\)See the appendix for a full lexical entry, modelled after semantics of belief attribution developed in Heim (1992). Once our entry is spelled out, the CCP will add a further definedness condition, viz. that \( [K_m(\phi \{X\})] \) is defined on context \( c \) only if \( c \) satisfies \( K_m(X) \). This would mean that (28), eg. presupposes that Mary knows that John has a sister. Crucially, this definedness condition is not stipulated, but follows from the basic compositional semantics we assign to know. Thus, from two assumptions: (i) the basic definedness condition of factivity, and (ii) the semantic contribution of know, we derive two new definedness conditions.
3. Mary knows that if John flies to Toronto, he has a sister

The first step in the update is to check for definedness. This means we check whether $c$ satisfies the complement of $know$, i.e. we check whether $c[\text{if John flies to Toronto, he has a sister}] = c$. Since $k = 0$, i.e. since the local context that needs to satisfy $[\text{if John flies to Toronto, he has a sister}]$ is just $c$ itself, and not some more complex context of the form $c[\phi_1] \ldots [\phi_k]$, $k > 0$, there is no option for strengthening. Our procedure generates only the following singleton set as the accommodation hypothesis space: $\{\text{if John flies to Toronto, he has a sister}\}$. This is the reason why there is no strengthening under $know$.

4. Brief Comparison with the Binding Theory of Presupposition

My analysis of presupposition accommodation is, like the binding theory (van der Sandt (1992), Geurts (1999)), rather syntactic in nature. I believe there is no escape from this conclusion. Geurts’s critique of the satisfaction theory teaches us that we have to take alternatives for accommodation seriously. Moreover, the binding theory not only takes formal alternatives seriously, but it also proposes an explicit algorithm which, given any sentence, produces a finite set of accommodation possibilities. Now that the satisfaction theory has a proposal in place for predicting the space of accommodation possibilities, it makes it possible to compare the predictions of the two theories. Here, we can only point to some of the ways in which the theories differ in predictions.

First, consider again conditionals of the form $\langle \text{if } \phi, \text{ then } \psi(X) \rangle$, like (1) and (2):

1. If John flies to Toronto, his sister will pick him up from the airport

2. If John is a scuba diver, he’ll bring his wetsuit

I predict that once accommodation possibilities are incorporated such sentences can only have two interpretations each, which can be paraphrased as below:

(29) John has a sister and if he flies to Toronto, his sister will pick him up from the airport

---

20 Kai von Fintel (p.c.) has raised the question of the extent to which my proposal counts as a version of the satisfaction theory, given that it uses an additional level of representation (CCPDs). Although I deviate from the letter of the satisfaction theory, I leave it to others to judge the extent to which this proposal remains in the spirit of the theory. For what it’s worth, I believe my proposal constitutes a somewhat conservative extension of the theory, once we take seriously the notion of CCPs as specifying “instructions” for context change.

21 At the level of accommodation + content.
(30) If John flies to Toronto, then he has a sister and she will pick him up from the airport

(31) John has a wetsuit and if he’s a scuba diver, he’ll bring his wetsuit

(32) If John is a scuba diver, he has a wetsuit and will bring it

Of course, (29) is the preferred interpretation of (1) (which corresponds to accommodation of $X$), and (32) is the preferred interpretation of (2) (which corresponds to accommodation of $⌜if \phi \text{ then } X⌝$). In general, we predict that $⌜if \phi \text{, then } \psi\{X\}⌝$ can only be interpreted in one of two ways:

(33) $⌜X \text{ and (if } \phi \text{, then } \psi\{X\}⌝$\n
(34) $⌜if \phi \text{, then (}X \text{ and } \psi\{X\}⌝$

The binding theory predicts these two readings, plus a third, the so-called “intermediate accommodation” reading:

(35) $⌜if X \text{ and } \phi \text{, then } \psi\{X\}⌝$

In (1) and (2), this would correspond to the following paraphrase:

(36) If John has a sister and he flies to Toronto, his sister will pick him up from the airport

(37) If John has a wetsuit and is a scuba diver, he’ll bring his wetsuit

As far as I can tell, conditionals $⌜if \phi \text{, then } \psi\{X\}⌝$ don’t generate such a reading.\(^{22}\)

A second issue arises with the binding theory’s binding/accommodation procedure. For example, if in the antecedent of a conditional a discourse referent is introduced by an indefinite, and the consequent contains a pronoun/definite description, then both the pronoun and the definite description should prefer to be read as “bound” by the discourse referent. At least, nothing should rule out such a reading. However, the following example shows this to be a problematic prediction:

Context: John is married to three women, though we are fully ignorant about their nationalities.

\(^{22}\)For more debate on the issue of intermediate accommodation see Geurts and van der Sandt (1999), Beaver (2001, 2004), von Fintel (2004a, 2006).
(38) If John is married to an American, she is a great cook

(39) #If John is married to an American, his wife is a great cook

In (39), the binding/accommodation procedure should allow his wife to ignore the other wives and pick up the American introduced in the antecedent, just as it allows she to do so in (38). The satisfaction theory on the other hand is not tied to such a prediction. In fact, it makes it rather explicit that the analogy between pronouns and definites should not be pushed too far (cf. Heim (1982)).

Much more deserves to be said here. I haven’t shown how my definition of local contexts generalizes beyond connectives (e.g., to quantifiers and attitude predicates). I also need to respond to the charge that CCPDs are, to some degree, stipulated (e.g., Schlenker (2007), among others). I also haven’t said how the alternatives I offer here might be usable by other theories that predict conditional presuppositions.

5. Appendix

Recursive Definition of Local Contexts Let $W$ be the set of all worlds, $\phi$, $\psi$ sentences. Any $c \subseteq W$ is a local context. Then, for any local context $c^*$: (i) $c^* [\phi]$ is a local context, (ii) $c^* - c^* [\phi]$ is a local context, (iii) $c^* [\phi] \cup c^* [\psi]$ is a local context, (iv) nothing else is a local context.

The CCP of Knowledge Attribution Sentences $c[K_m(\phi)] = \{w \in c : Dox_m(w) [\phi] = Dox_m(w)\}$, where $Dox_m(w) = \{w' \in W : w R_m w'\}$, where $R_m$ is the accessibility relation for Mary. Since the entry is for know, the relation will be reflexive, symmetric, and transitive, validating an S5 modal logic. It follows from this CCP, plus what we said in the text, that $c[K_m(\phi \{X\})]$ is defined only if: (i) $c[X] = c$, (ii) $c[\phi] = c$, (iii) $c[K_m(X)] = c$.
