

# On pragmatic uses of demonstratives: The case of pragmatic discourse anaphora in Czech\*

Radek Šimík  
University of Potsdam

October 7, 2015  
[First draft]

## 1 Introduction

Demonstratives (DEM) typically have a clear semantic contribution: they shift the property denoted by their NP complement to the single individual in its extension (relative to some situation), see (1). On this Fregean view (Frege 1892; Heim 1991), demonstratives are definite articles of sorts: even if their semantic contribution is more complex, they always have something like (1) at their core (Wolter 2006; Elbourne 2008). Examples of what I will call *canonical uses* of demonstratives (whence DEM<sub>can</sub>) are provided in (2): a deictic use in (2-a) and an anaphoric use in (2-b).

- (1) For some situation  $s$   
 $\llbracket \text{DEM}_{\text{can}} \text{NP}_{\langle e, st \rangle} \rrbracket = \iota x \llbracket \text{NP} \rrbracket (x)(s)$
- (2) **Canonical uses of demonstratives**
- Look at that/this ( $\approx$  the) man.
  - We were introduced to Senator Johnson. This ( $\approx$  The) politician has been in office since 2011.

There are uses of demonstratives, however, which defy this simple view. I will call them *pragmatic uses* (DEM<sub>prag</sub>) because they do not appear to change the core semantics of their NP complement (formally captured in (3)): proper names remain proper names (4-a), generics remain generics (4-b), and indefinites remain indefinites (4-c).<sup>1</sup>

- (3)  $\llbracket \text{DEM}_{\text{prag}} \text{NP} \rrbracket = \llbracket \text{NP} \rrbracket$
- (4) **Pragmatic uses of demonstratives**
- This ( $\approx$  The) Henry Kissinger is really something! (Lakoff 1974)
  - Those ( $\approx$  The) IBM ThinkPads are quite popular. (Bowdle & Ward 1995:33)
  - A few years ago, there was this ( $\approx$  the) hippie, long-haired, slovenly. (Prince 1981:233)

The present paper sets out to achieve two goals—an empirical and a theoretical one. On the empirical side, I will present data from Czech (novel in the formal literature), where pragmatic uses

---

\*This paper was presented at FASL24 at New York University and at SuB20 in Tübingen. I am grateful to the audiences for their suggestions and critical remarks. I especially profited from the comments of Pavel Caha, Amy Rose Deal, Patrick Grosz, Itamar Kastner, and Ora Matushansky. All errors are mine.

<sup>1</sup>By using a single label for these uses, I do not intend to imply that they should receive a unified treatment.

of demonstratives are particularly productive. Though affective uses of demonstratives are well-attested in Czech (see section 4 for examples),<sup>2</sup> I will concentrate on a discourse anaphoric use: a case of what one could call *pragmatic discourse anaphora*. The core data will be introduced shortly, in section 2. On the theoretical side, I will propose a new analysis of demonstratives, inspired by Elbourne (2008), Schwarz (2009), and Simonenko (2013), which, on the one hand, captures the intimate connection between demonstratives and definite articles and, on the other, offers enough flexibility to model the pragmatic uses of demonstratives. The analysis (presented in section 3) is designed to capture the particular case of pragmatic anaphora in Czech, but section 4 will offer a speculation on how the analysis could be extended to pragmatic uses of demonstratives in general. Section 5 summarizes the paper and discusses some open issues.

## 2 Czech data

### 2.1 Background information on the Czech demonstrative system

Czech has a whole variety of demonstrative expressions. The inflectional paradigm of the basic demonstrative determiner *ten* (to be glossed as DEM) is provided in Table 1.

	SG.MASC	SG.NEUT	SG.FEM	PL (PL.ANIM)
NOM	ten	to	ta	ty (ti)
ACC	toho	to	tu	ty
GEN	toho	toho	té	těch
PREP	tom	tom	té	těch
DAT	tomu	tomu	té	těm
INSTR	tím	tím	tou	těmi

Table 1: The paradigm of the demonstrative determiner *ten*

Besides the determiner *ten* (which can function as a pronoun as well) there is a range of demonstratives for various ontological categories (summarized in Table 2): *tady* ‘here’ (locative proximal), *tam* ‘(to) there’ (locative/directional distal), *sem* ‘to here’ (directional proximal), *tudy* ‘via (t)here’ (path), *tolik* ‘so/this many/much’ (amount), *ted’* ‘now’ (temporal present), *tehdy* ‘(back) then’ (temporal past), *tak* ‘so’ (manner), and *takový* ‘such’ (kind). Most of these demonstratives have a deictic/indexical use (the exception being the temporal past *tehdy*) and many have an anaphoric use (in particular the determiner/pronominal *ten*, the distal locative/directional *tam*, the amount-denoting *tolik*, the past temporal *tehdy*, the manner-denoting *tak*, and the kind-denoting *takový*). In addition, there are a number of morphemes that can modify these demonstratives (sometimes called “reinforcers”; see Roehrs 2010 or Marušič & Žaucer 2012), with some (more or less obvious) gaps in the paradigm of the different ontological categories: the postfixes *-hle* (deictic (proximal)) and *-to* (deictic proximal/anaphoric), and the semi-free morphemes *tady* ‘here’ (deictic proximal) and *tam* ‘there’ (deictic distal).<sup>3</sup> The last mentioned ones are demonstratives themselves, as can be seen by the capacity to be modified by *-hle*.<sup>4</sup>

<sup>2</sup>The “emotive” function of demonstratives was discussed as early as in Mathesius (1926) and has been acknowledged in the Czech linguistic tradition ever since. For a more recent overview and references, I refer the reader to Berger (1993: section 5.1).

<sup>3</sup>A “postfix” is a suffix that always attaches last, even after inflectional endings. In this sense, it is a borderline case between suffixes and clitics.

<sup>4</sup>The demonstrative determiner *ten* can be doubled when combined with *-hle*, giving rise to expressions like *tenhleten*, *tohohletoho*, etc. The Slovenian version of this doubling construction was studied by Marušič & Žaucer (2012).

	BASIC	DEIC(.PROX)	DEIC.PROX/ANAPH	DEIC.PROX	DEIC.DIST
DET/PRON	ten	tenhle	tento	tady(hle) ten	tam(hle) ten
LOC.PROX	tady	tadyhle	%tadyto	*	*
LOC/DIR.DIST	tam	tamhle	%tamto	*	*
DIR.PROX	sem	semhle	*	*	*
PATH	tudy	tudyhle	%tudyto	tady(hle) tudy	tam(hle) tudy
AMOUNT	tolik	%tolikhle	*	*	*
TEMP.PRES	ted'	%ted'hle	*	*	*
TEMP.PAST	tehdy	*	*	*	*
MANNER	tak	takhle	takto	%tady tak	*
KIND	takový	takovýhle	takovýto	%tady takový	*

Table 2: Demonstrative modifiers as applied to different ontological categories

For a comprehensive discussion of the Czech demonstrative system and an extensive literature overview, I refer the reader to Berger (1993). The present paper will concentrate on the determiner *ten*, as it is the only one that allows for pragmatic uses. See section 3.3 for a brief speculation on how *tento* could fit into the proposal.

## 2.2 Canonical vs. pragmatic anaphoric uses of *ten*

In its discourse anaphoric use, the demonstrative determiner *ten* exhibits a systematic ambiguity. Upon the canonical reading, it presupposes the existence of a unique referent in the extension of its NP complement. The uniqueness often results from the process of an “easy” accommodation, relying on the common knowledge of the interlocutors.<sup>5</sup> This accommodation may give rise to the intuition that the unique referent is being selected from a non-singleton set of potential referents (the extension of the NP prior to the accommodation). Upon the pragmatic reading, there is no uniqueness presupposition. Instead, the NP complement remains semantically (type-wise) intact and the demonstrative contributes a reminder that the NP complement or even the utterance in which it occurs is part of previous *common discourse*, which can be defined (in allegiance to Stalnaker’s 1970 concept of common ground) as the set of utterances that the interlocutors know have been made.<sup>6</sup>

In the examples below, the (a)-readings are canonical and the (b)-readings are pragmatic. The canonical readings should be understood by readers straightforwardly, as they are (presumably) present in every language. The only example where the canonical reading is very difficult to find a context for is (6). It would be felicitous in a situation where temperature measurement is normally associated with an additional parameter that can take different values. Suppose, for instance, the counterfactual scenario in which temperatures come in different colors: 35 degrees (just as any other temperature) can be blue, red, etc. In that case, the reading (6-a) could be quite natural, saying, e.g, that it is supposed to be blue (rather than red) 35 degrees tomorrow.

But let us turn to the pragmatic readings, which I have had troubles explaining to people who do not speak Czech. For that reason, I would like to spell out a concrete context in which the pragmatic reading of each example is felicitous. For ease of presentation, suppose that the utterances are made

<sup>5</sup>The accommodation is modeled either by intersecting the NP denotation with a covert property or by providing a suitable value for a situation variable relative to which the NP is interpreted. I adopt the latter view here without an argument.

<sup>6</sup>To the best of my knowledge, Adamec (1983) was the first one to discuss pragmatic anaphoric uses of demonstratives in Czech (further noting that they do not exist in Russian). Adamec recognizes the reminding function of this use of demonstratives and notices that what is being reminded is typically not just the complement NP itself but rather a whole utterance that was made about it. This brings him to the conclusion that “reminding” demonstratives are a sort of propositional modifiers, akin to discourse particles.

by Ann in a conversation with Bob. Consider (5) first: Ann and Bob are discussing a serious problem they have with their landlord. Bob suggests that they could seek advice with their common friend Mirek. Ann is not convinced at first but then she realizes that she (recently) heard that Mirek is a lawyer, uttering (5) as an expression of this realization. The speaker-oriented particle *vlastně* contributes to this “sudden realization” reading. Ad (6): Ann and Bob put together plans for tomorrow. Bob suggests that they could go play basketball. Ann counters that it might be too hot for basketball by uttering (6-a), reminding Bob of the weather forecast they heard recently. Ad (7): Ann and Bob are partners and are at a party. It is getting late and Bob suggests to go home. But Ann still had not managed to speak to their common friend Jana (who is also at the party) and utters (7), in order to remind Bob that Ann planned to speak to her. Ad (8): Suppose that Bob suggests that the linguistics department takes over some faculty-level administrative burden, after which Ann counters with (8), reminding Bob that the department still does not have a secretary (as A believes Bob had surely heard).<sup>7</sup>

- (5) Mirek je vlastně **ten právník**. DEM + PREDICATIVE NP  
 Mirek is PART DEM lawyer  
 a. ‘Mirek is the lawyer [that we met at the party yesterday].’  
 b. ‘Mirek is a lawyer [as I’ve just realized we’ve heard].’
- (6) Zítřa má být **těch 35 stupňů**. DEM + DEGREE-DENOTING NP  
 tomorrow has be.INF DEM 35 degrees  
 a. #‘Tomorrow, it’s supposed to be those 35 degrees [and not some other 35 degrees].’  
 b. ‘Tomorrow, it’s supposed to be 35 degrees [remember, we spoke about it supposing to be 35 degrees tomorrow].’
- (7) Potřebovala bych si promluvit s **tou Janou**. DEM + REFERENTIAL NP  
 need SUBJ.1SG REFL speak.INF with DEM Jana  
 a. ‘I need to speak with that Jana [that we met yesterday].’  
 b. ‘I need to speak with Jana [remember, we spoke about speaking to her].’
- (8) Katedra lingvistiky ještě hledá **tu sekretářku**. DEM + NON-SPECIFIC NP  
 department linguistics still looks.for DEM secretary  
 a. ‘The linguistics department is still looking for the secretary [that disappeared yesterday].’  
 b. ‘The linguistics department is still looking for a secretary [remember, we spoke about them needing one].’

There is a way of distinguishing the canonical reading from the pragmatic one by adding further discourse. In particular, the two readings are each associated with a distinct reaction to a presupposition failure. If the uniqueness presupposition of the canonical reading is not satisfied, the hearer reacts by wondering about the identity of the individual that the speaker intended to refer to. A reaction to the pragmatic reading, on the other hand, involves expressing the inability to recollect a relevant utterance about the NP complement. Below, I provide particular examples that complement (7): (9-a) is a possible reaction to reading (7-a) and (9-b) is a possible reaction to (7-b).

---

<sup>7</sup>As noticed by Amy Rose Deal, the pragmatic reading of example (8) could be analyzed as a case of modal subordination. I admit that this is the case and include the example only for the sake of completeness.

(9) **Expressing presupposition failures on the two readings**

- a. Počkej, s kterou Janou?  
wait with which Jana  
'Wait a minute, with which Jana?'
- b. Počkej, nevzpomínám si, že bys mi říkala, že si potřebuješ promluvit  
wait NEG.remember.1SG REFL that SUBJ.2SG me said that REFL need.2SG speak  
s Janou.  
with Jana  
'Wait a minute, I can't remember you telling me that you wanted to speak with Jana.'

Before we move on, I should point out that the utterance that is being reminded of need not necessarily be (a part of) the utterance in which the demonstrative occurs. Consider example (10), which can be uttered in the same situation as (7) (described in the paragraph above (8)), contributing the same reminder. This indicates that it is inadequate to think of the pragmatic demonstrative as a propositional modifier (an idea put forth by Adamec 1983), one that would take the whole proposition as its argument and contribute the comment that this proposition has been uttered.

- (10) Tu Janu nechám na jindy.  
DEM Jana let.1SG for other.time  
'I will postpone [speaking with] Jana for some other time. [remember, we spoke about speaking to her].'

To sum up: The Czech demonstrative *ten*, on top of serving the standard anaphoric function, can be used as a reminder of an utterance in the common discourse (and by extension the semantics it conveys) which is somehow “about” the NP complement of the demonstrative. The NP complement can be of any type (e.g., property-denoting, predicative, referential, non-individual-denoting) and its type remains unaffected by the demonstrative. The utterance that is being referred back to by help of the demonstrative must be, in one way or another, relevant to the presently made utterance. Although it is frequently the case that the reminded-of utterance is semantically identical to the one that is just being made, this is by no means a necessity.

### 3 Analysis

The analysis I propose intends to find an answer to the following questions raised by the dataset in section 2: 1. How can it be that a single demonstrative determiner sometimes does and other times does not have a semantic contribution? 2. How is it possible that a demonstrative refers back to a whole utterance rather than just to the referent/denotation of the demonstrative description?<sup>8</sup>

In a nutshell, the proposal goes as follows: Demonstratives are lexical items that can spell-out two semantic components (following Elbourne 2008; Schwarz 2009; Simonenko 2013): the uniqueness presupposition (along with a iota-type-shift) and a relational component—establishing a relation (identity by default) between the denotation of the demonstrative description and an entity being pointed at (in a literal or metaphorical sense). These components are in principle independent of one another, making it possible for the demonstrative to spell-out either both at once (canonical use) or the relational component only (pragmatic use). (Spelling out only the uniqueness component is blocked by the availability of a definite article, which will become clear shortly.) Finally, I will

---

<sup>8</sup>The term “demonstrative description” (built after “definite description” and adopted from Wolter 2006) refers to an NP with a demonstrative determiner, e.g. *that man*.

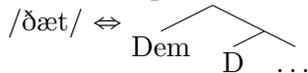

argue that the key to the understanding of the observed anaphoric reference to utterances, despite the NP attachment, lies in the notion of a deferred ostension (Quine 1969; Nunberg 1979; Elbourne 2008).

### 3.1 Syntax and spell-out

My syntactic account relies on the theory of nanosyntax (Starke 2009; Caha 2009), which offers an elegant way of dealing with lexical polysemy and morphological syncretism and hence is suitable for the situation we face: an ambiguity of a demonstrative determiner. According to nanosyntax, the syntactic information of a lexical item is represented as a syntactic constituent or a sequence of heads (rather than a bundle of features as, for instance, in distributed morphology). The post-syntactic lexical insertion respects the superset principle, according to which a lexical item matches a piece of syntax (and hence can be inserted) if the syntactic representation of the item is a superset of that piece of syntax. The insertion is further constrained by the so called elsewhere principle (Kiparsky 1973), which prefers the insertion of the lexical item which provides the best fit (in this case: the smallest superset) of the given piece of syntax.<sup>9</sup>

Let us now get back to demonstratives. I propose that the lexical entry of a demonstrative or more precisely the phonology-syntax association in that entry is as in (11): the exponent /ðæt/ corresponds ( $\Leftrightarrow$ ) to the sequence of two heads—Dem and D.<sup>10</sup> For comparison, I provide the lexical entry of a definite article, whose exponent /ðə/ corresponds to D only.

(11) **Lexical representation of *that***

(12) **Lexical representation of *the***

Suppose now that the syntax can generate all the structures in Table 3. What are the possible exponents of these structures given the lexical entries above and the nanosyntactic principles? The syntactic representation of the demonstrative matches (is a superset of) all the structures and therefore the demonstrative could in principle spell them all out. However, it can only spell out Dem+D and Dem; it cannot spell out D alone because it finds a better match in the syntactic representation of the definite article. In other words, the demonstrative is ruled out from spelling out D on the grounds of the elsewhere principle.<sup>11</sup> The definite article, in turn, is only a superset of D alone and cannot spell out any structure with Dem.<sup>12</sup>

<sup>9</sup>For reasons of space, I cannot provide more background information on nanosyntax. Nevertheless, I beg the reader to bear with me, the actual application is fairly simple.

<sup>10</sup>Much of the syntactic literature assumes the opposite order/hierarchy, namely one where D scopes over Dem. See footnote 18 and the associated main-text discussion for a semantic reason why the Dem over D order is preferred in the present approach.

<sup>11</sup>There is a prediction for articleless languages, which should be able to spell out D by a demonstrative because there is no article to block it. This prediction is relativized, however, by one’s assumption about the syntax of articleless languages. In particular, it holds only if articleless languages possess/project the category D in the first place (cf. Bošković 2009).

<sup>12</sup>Some readers may wonder what blocks spelling out D by *the* and subsequently spelling out Dem by *that*, giving something like *that the NP* as a result. There are at least two ways to rule this out: by the minimize exponence principle (Siddiqi 2006), which forces fewer spellouts whenever possible (*that the* is thus blocked because *that* achieves the same in a single step), or by the assumption that spellout is cyclic, bottom-up, and that subsequent spellout steps “override” previous ones (under structure preservation); see Starke’s (2009) “biggest wins” theorem.

LABEL	STRUCTURE	EXPONENT		TYPE OF DEM
<b>Dem+D</b>		<i>that</i>	( <i>the</i> ruled out by superset)	canonical
<b>Dem</b>		<i>that</i>	( <i>the</i> ruled out by superset)	pragmatic
<b>D</b>		<i>the</i>	( <i>that</i> ruled out by elsewhere)	

Table 3: Structures and their exponents

I have demonstrated how a single lexical entry for a demonstrative can spell out two different syntactic structures, namely Dem+D and Dem alone. What is important is that there are potentially distinct lexical entries for phonological and semantic purposes: even if a single exponent spells out a complex structure, such as Dem+D, it can hold that each individual component of that structure gets interpreted individually, i.e., Dem and D each receives its own interpretation. Thus, spelling out two different syntactic structures—Dem+D or Dem—results in two different, albeit related meanings—the canonical one and the pragmatic one, respectively (as indicated by the last column of Table 3). This is the first core building block in the answer to our first question: How can it be that a single demonstrative sometimes does and other times does not have a semantic contribution? I now move on to the semantic side of things.

### 3.2 Semantics

On the present approach, asking what the denotation of a demonstrative is amounts to asking what the denotation of its possible components is, i.e., D and Dem. But before we turn to discussing the interpretation of these individual heads, I will provide a background on Schwarz’s (2009) analysis of strong definite articles and Elbourne’s (2008) analysis of demonstratives, on which the present approach builds.

#### 3.2.1 Background: Schwarz (2009) and Elbourne (2008)

Schwarz and Elbourne both have the idea that demonstratives (or strong definite articles) are semantically more specified versions of (weak) definite articles: they contribute what articles do, but they do more than that.<sup>13</sup> The definite-article contribution is essentially the iota type-shift (property  $\rightarrow$  entity; Partee 1987) and the uniqueness/maximality presupposition it comes with. A particular situation-semantic implementation of this is in (13) (relying on Schwarz’s assumptions).

$$(13) \quad \llbracket \text{D/the} \rrbracket = \lambda s_s. \lambda P_{\langle s, et \rangle} : |P(s)| = 1. \iota x [P(s)(x)]$$

The additional contribution specific to demonstratives is what I call here the relational presupposition. The relational presupposition requires that the denotation of a demonstrative description be related (by a two-place relation  $R$ ) to something in extra-linguistic reality or in previous discourse. According to Schwarz,  $R$  is always the identity relation ( $=$ ) and the relevant entity ( $y$ ) is a referent introduced in previous discourse. The resulting semantics is in (14).

$$(14) \quad \llbracket \text{the}_{\text{strong}}/\text{that} \rrbracket^g = \lambda s_s. \lambda P_{\langle s, et \rangle}. \lambda y_e : |P(s)| = 1. \iota x [P(s)(x) \wedge x = y]$$

<sup>13</sup>Schwarz (2013) hypothesizes that his 2009-analysis of strong definite articles could be applied to demonstratives in articleless languages.

It provides the basis for an adequate account of canonical anaphoric uses of definite or demonstrative descriptions: on the one hand, they are run-of-the-mill descriptions, on the other, they establish an identity relation to a previously mentioned referent. Consider example (2-b), repeated in (15). The meaning of the description is in (16).

(15) We were introduced to Senator Johnson. This/The politician has been in office since 2011.

(16)  $\llbracket \llbracket \llbracket \text{[this/the } s_2 \text{] politician} \rrbracket y_1 \rrbracket \rrbracket^g = \iota x [\text{politician}'(g(2))(x) \wedge x = g(1) = \text{Johnson}']$

Elbourne’s proposal is more complex but also more general, as it does not specify the value of the relation  $R$ .<sup>14</sup> The lexical entry of a demonstrative in this system (abstracting away from the proximity/distality parameter) is provided in (17). Apart from a number of technical details, the entry differs from Schwarz’s in that it involves an additional argument—the relation  $R$  between an entity ( $x$ ) and an individual concept ( $\lambda s'.z$ ). This relation corresponds to the identity relation in Schwarz’s system (and indeed, the identity relation is the default value of the relational argument). The entity is the deictic component of the demonstrative (what is being pointed at) and corresponds to Schwarz’s discourse referent ( $y$ ). The individual concept corresponds to the denotation of the whole demonstrative description.

(17)  $\llbracket \text{[DEM]} \rrbracket = \lambda x_e. \lambda R_{\langle e, \langle se, st \rangle \rangle}. \lambda P_{\langle se, st \rangle}. \lambda s_s. \iota z [R(x)(\lambda s'.z)(s) \wedge P(\lambda s'.z)(s)]$

Consider example (18), a standard case of deictic use of demonstratives. The interpretation of *that man* is given in (19). In this case, the value of the entity argument ( $i_1$ ) provided by the assignment function  $g$  is the individual pointed at, i.e. John. The value of the relational argument ( $R_2$ ) is the identity relation. This means that the individual denoted by the demonstrative description *that man* is identical to John.

(18) Look at that man [GESTURE AT JOHN].

(19)  $\llbracket \llbracket \llbracket \llbracket \text{[that } i_1 \text{] } R_2 \rrbracket \text{ man} \rrbracket \rrbracket^g = \lambda s. \iota x [\text{John}' = x \wedge \text{man}'(x)(s)]$

Let us now look at a case that substantiates the variable nature of the relational component, i.e., a case where the relation has a different value than identity. One of the core arguments comes from a phenomenon called *deferred ostension* (early observations date back to Quine 1969 and Nunberg 1979), which is characterized by a situation “in which the speaker demonstrates one thing in order to refer to another.” (Elbourne 2008:439) An example is given in (20), where the speaker intends to refer to donkeys by pointing at empty fields. Obviously, the relation between what is being referred to and what is being pointed at is not the identity relation, as in (18). Rather, it is one that corresponds to the predicate *is kept in*. The denotation of *this/that donkey* (again, ignoring the proximity/distality parameter) is provided in (21).

(20) This donkey [GESTURE AT FIELD A] is healthier than that donkey [GESTURE AT FIELD B].  
(Elbourne 2008:439)

(21)  $\llbracket \llbracket \llbracket \llbracket \llbracket \text{[this/that } i_1 \text{] } R_2 \rrbracket \text{ donkey} \rrbracket \rrbracket \rrbracket^g = \lambda s. \iota x [\text{is.kept.in}'(\text{field.A}')(x)(s) \wedge \text{donkey}'(x)(s)]$

I will show how the concept and mechanism of deferred ostension can be utilized in answering our second question concerning pragmatic demonstratives: How can it be that a demonstrative description anaphorically points to something else (an utterance) than what it denotes (an NP denotation)?

<sup>14</sup>Conceptually, Elbourne’s proposal builds on Nunberg (1993).

Finally, I would like to sketch how [Elbourne](#) proposes to account for anaphoric uses of demonstrative descriptions, as it will be relevant for my own proposal.<sup>15</sup> Unlike [Schwarz](#), who assumes that the element that enters the (identity) relation with the denotation of the demonstrative description is a *discourse referent* (a metalinguistic entity), [Elbourne](#) proposes that it is a word/phrase *occurrence* (an object language entity). For reasons of terminological consistency, I replace the term occurrence with the term utterance. An utterance is, according to [Elbourne](#), always of type  $e$ . For this reason, it can act as the first argument of the relevant relation. And what is the value of this relation in demonstrative anaphora? It is a more specific version of the classical interpretation function  $\llbracket \cdot \rrbracket$ , namely a function that interprets nouns and NPs:  $\llbracket \cdot \rrbracket_{\text{NP}}$ . This function is of type  $\langle e, \langle se, st \rangle \rangle$ : it takes an object-language NP (type  $e$ ) and returns a property (a function from individual concepts  $\langle s, e \rangle$  to propositions  $\langle s, t \rangle$ ). In more accessible terms, the relation is *has the property denoted by*. Technically, anaphora in [Elbourne](#)'s account is a case of deferred ostension, simply because the relation involved is not identity. Consider, once again, our example with an anaphoric demonstrative description—*this politician*. If the assignment function assigns the utterance *Senator Johnson* to  $i_1$  and  $\llbracket \cdot \rrbracket_{\text{NP}}$  to  $R_2$ , we arrive at the interpretation in (23).

(22) We were introduced to Senator Johnson. This politician has been in office since 2011.

(23)  $\llbracket \text{this } i_1 R_2 \text{ politician} \rrbracket^g$   
 $= \lambda s \iota x [\text{has.the.property.denoted.by}'(\text{Senator Johnson})(x)(s) \wedge \text{politician}'(x)(s)]$

In sum, just as deictic demonstratives establish a relation between something in the extra-linguistic reality and the denotation of the demonstrative description (typically but not always identity), anaphoric demonstratives establish a relation between something in previous discourse and the denotation of the demonstrative description.

### 3.2.2 Proposal: Semantics of D and Dem

In section 3.1, I proposed that demonstratives are lexically composed of two heads—Dem and D—and that, due to nanosyntactic principles, can stand either for Dem+D or for Dem alone. Understanding the semantics of demonstratives in this system therefore amounts to understanding what the individual semantic contributions of Dem and D are and how they interact. The core idea is that the two components of demonstratives (or of strong definite articles) postulated by [Elbourne](#) (2008) (and [Schwarz](#) 2009), namely uniqueness and relationality, are distributed over the two heads that the demonstrative can spell-out: D and Dem, respectively.<sup>16</sup> It follows that if a demonstrative spells out Dem alone, the uniqueness component will be missing. This is the basic (and general) tool that the present analysis offers for the understanding of pragmatic readings of demonstratives. Let us now move on to the particular semantic proposal.

Concerning D, I have nothing new to contribute. I simply assume that D has the semantic of a Fregean definite article: it contributes the uniqueness presupposition and shifts properties to individuals. The semantic lexical entry is repeated below.

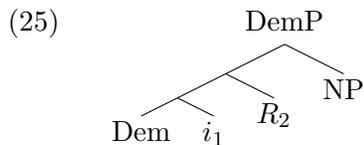

(24)  $\llbracket \text{D} \rrbracket = \lambda s_s . \lambda P_{\langle s, et \rangle} : |P(s)| = 1 . \iota x [P(s)(x)]$

The crucial contribution of Dem is the relational component, establishing a relation of the kind described above. What Dem must lack, on the other hand, is the uniqueness presupposition and the type-shifting capacity. One reason for this is theory-internal: uniqueness plus type-shifting is

<sup>15</sup>[Elbourne](#) only explicitly treats donkey anaphora (section 3.8), but as far as I can tell, the proposal carries over to run-of-the-mill discourse anaphoric uses.

<sup>16</sup>See [Simonenko](#) (2013) for a similar, albeit differently motivated proposal.

a function attributed to D and it would make little sense to reiterate it in Dem. Another reason is empirical: pragmatic uses of demonstratives need not impose any uniqueness requirement (as established in section 2) and appear to leave the type of their NP complement intact (sections 1 and 2). Moreover, various kinds of NPs can be complements to pragmatic demonstratives. All these considerations necessitate type-flexibility upon Dem’s NP-argument and consequently upon the second argument of the relational variable. We arrive at the picture in (25): Dem is a three-place function, taking an index  $i_1$  (type  $e$ ), a relation  $R_2$  (type  $\langle e, \langle \alpha, st \rangle \rangle$ , for any type  $\alpha$ ), and an NP (type  $\alpha$ ) as its arguments, and returns the meaning of its NP argument (type  $\alpha$ ) as its value. Assuming that the relational contribution is presuppositional in nature, we can say that Dem functions as a partial identity function (type  $\langle \alpha, \alpha \rangle$ ) upon its NP argument.

The corresponding lexical entry of Dem is in (26). It presupposes that the value of  $i_1$  is related by the value of  $R_2$  to the denotation of the NP argument (in the utterance situation  $s_u$ ) and returns the denotation of the NP argument as its final value.<sup>17</sup>

$$(26) \quad \llbracket \text{Dem} \rrbracket^{g, s_u} = \lambda x_e. \lambda R_{\langle e, \langle \alpha, st \rangle \rangle}. \lambda X_\alpha : R(x)(X)(s_u). X$$

Before we turn to an application of this proposal to the Czech data from section 2, let us make explicit how the system works in the two core cases: Dem+D and Dem only. In the former case, Dem selects a definite description (type  $e$ ) and returns its denotation if it is related by the contextually determined relation to the contextually determined entity.<sup>18</sup> In the latter case, Dem selects an NP (whatever its denotation is) and returns its denotation if it is related by the contextually determined relation to the contextually determined entity. There are no restrictions on the denotation of this “bare” NP or, more precisely, the restrictions are independent of the present proposal. The NP could be property-denoting (type  $\langle s, et \rangle$ ), individual- or kind-denoting (type  $e$  or  $\langle s, e \rangle$ ), and in principle also quantificational (type  $\langle \langle s, et \rangle, t \rangle$ ), a case I leave aside in this paper.

### 3.2.3 Application to anaphoric demonstrative descriptions in Czech

Let me start with a brief reminder of the empirical situation described in section 2. We saw that DEM+NP combinations in Czech yield a systematic ambiguity between canonical demonstrative description readings and what I called pragmatic readings. On the pragmatic reading, the demonstrative (i) leaves the semantics of the NP complement intact and (ii) contributes a reminder that there is a relevant utterance in previous common discourse that was about the denotation of the NP. This is schematically summarized in (27) for two of the cases discussed in section 2.

$$(27) \quad \begin{array}{ll} \text{a.} & \llbracket \text{DEM}_{\text{prag}} \text{NP}_{\langle s, et \rangle} \rrbracket = \llbracket \text{NP}_{\langle s, et \rangle} \rrbracket + \text{reminder of a relevant utterance about } \llbracket \text{NP}_{\langle s, et \rangle} \rrbracket \\ \text{b.} & \llbracket \text{DEM}_{\text{prag}} \text{NP}_e \rrbracket = \llbracket \text{NP}_e \rrbracket + \text{reminder of a relevant utterance about } \llbracket \text{NP}_e \rrbracket \end{array}$$

<sup>17</sup>I take the relational component to be presuppositional essentially for the purpose of exposition. As far as I am concerned, its exact semantic status is an open issue.

<sup>18</sup>This makes clear why Dem has to scope over D rather than the other way around. If Dem is to establish a relation between the DP (or the whole demonstrative description in previous approaches) and some entity, then D has to apply before Dem. Alternatively, if syntax necessitated a D over Dem hierarchy, then D would have to be a semantic argument of Dem, which would require a serious reformulation of D’s contribution to the compositional semantics.

Consider now, first in informal terms, how the two observations are accounted for in the present analysis. The first observation is accounted for by the assumption that pragmatic demonstratives correspond to (spell out) Dem alone (the following correspondences hold:  $\text{DEM}_{\text{prag}} \Leftrightarrow \text{Dem}$  and  $\text{DEM}_{\text{can}} \Leftrightarrow \text{Dem} + \text{D}$ ). Since Dem acts as a (partial) identity function, the semantics of the NP complement remains unaffected by Dem. The second observation is accounted for by the relational presupposition introduced by Dem, incorporating [Elbourne’s \(2008\)](#) insight about deferred ostension. I assume that the case at hand is indeed an instance of deferred ostension: the denotation of the demonstrative description equals the denotation of the NP, but what is being pointed at (metaphorically) is some relevant utterance in previous common discourse.<sup>19</sup> The relation implicated is an aboutness relation of sorts: the utterance is about the NP denotation.<sup>20</sup> One comment is in order before we move on to the formalization. Standard deferred ostension represents a demonstrative/indexical strategy of the speaker to help the hearer figure out the referent even in its absence in the utterance situation. The present application of deferred ostension is somewhat different because it does not serve the purpose of determining a referent or, more generally, denotation of a demonstrative description: the referent/denotation is clear enough to the hearer even without the demonstrative. What *does* it do then? By establishing a relation to previous common discourse, the speaker helps the hearer find a particular context in which the presently made utterance is relevant.

I will now present an application of the formal analysis to two particular examples (of the kind in (27)). Let us start with a case of DEM + proper name, representing the application of a demonstrative to a referential expression (type  $e$ ). As an example, take the demonstrative description *tou Janou* ‘that Jana’ in (28), repeated from (7).

- (28) Potřeboval bych si promluvit s **tou Janou**. DEM + REFERENTIAL NP  
 need subj.1sg refl speak.inf with DEM Jana  
 a. ‘I need to speak with that Jana [that we met yesterday].’  
 b. ‘I need to speak with Jana [remember, we spoke about speaking to her].’

Under its pragmatic reading (28-b), the meaning of the demonstrative *tou* equals the meaning of Dem alone. The meaning of *Janou* is simply the individual Jana. The relational presupposition contributed by Dem/*tou* is in (29-a); if it is satisfied, the denotation of the whole demonstrative description is equal to Jana, as captured in (29-b).

- (29) a.  $\llbracket [\text{DemP Dem } i_1 R_2 [\text{NP Janou}_e]] \rrbracket^{g,s_u}$  is defined if  
 in the utterance situation  $s_u$ , some relevant utterance in previous common discourse  
 $[ = g(1)]$  is about  $[ = g(2)]$  Jana. If defined, then  
 b.  $\llbracket [\text{DemP Dem } i_1 R_2 [\text{NP Janou}_e]] \rrbracket^{g,s_u} = \text{Jana}$

For comparison, consider the canonical reading (28-a). In this case, the demonstrative *tou* stands for (spells out) two heads: Dem and D. The structure to be interpreted is therefore the one in (30). The application of D to *Janou* results in a type clash: *Janou* is of type  $e$ , but D requires type

<sup>19</sup>This might in fact be too restrictive: It is possible to find scenarios where the interlocutors do not have the same utterance in mind. It seems enough if they know that there was a relevant utterance (possibly different for each interlocutor). This would call for a modification under which the deictic component (what is being pointed at) is modeled not as a variable that is free but that is existentially bound in a presupposition; see the modified lexical entry in (i).

(i)  $\llbracket \text{Dem} \rrbracket^{g,s_u} = \lambda R_{\langle e, \langle \alpha, st \rangle \rangle} . \lambda X_\alpha : \exists x_e [R(x)(X)(s_u)]. X$

<sup>20</sup>In the seminal work by [Reinhart \(1981\)](#), ‘being about something’ is a property of propositions. Yet, what a proposition is about is often only determined in a particular discourse, making utterances better candidates for the domain of ‘being about something’.

$\langle s, et \rangle$  from its NP argument. This coerces a type shift of *Janou* to the property  $\lambda s. \lambda x. x$  is Jana in  $s$ —a set of situation-individual pairs such that the individual(s) is/are Jana(s) in that situation. The uniqueness requirement introduced by D restricts the possible values for the resource situation ( $s_3$ ) to those in which there is a single Jana. As indicated in (28-a), the relevant situation can be one in which we spoke to Jana yesterday. This is the mechanism of domain restriction (down to a singleton) and it corresponds to the implicit choice of the right Jana (out of a potentially larger set of Janas).

$$(30) \quad [\text{DemP Dem } i_1 R_2 [\text{DP D } s_3 [\text{NP Janou}_e]]]$$

Taking the coercion into account, the meaning of the DP is in (31) and the meaning of the whole DemP, i.e., the expression *tou Janou*, on its canonical reading, is in (32). I leave aside what the particular value of the demonstrated entity and the corresponding relation could be.

- (31) a.  $\llbracket [\text{DP D } s_3 [\text{NP Janou}_{\langle s, et \rangle}]] \rrbracket^{g, s_u}$  is defined if there is a single Jana in the resource situation  $[ = g(3)]$ . If defined, then  
 b.  $\llbracket [\text{DP D } s_3 [\text{NP Janou}_{\langle s, et \rangle}]] \rrbracket^{g, s_u} = \iota x [\text{Jana}(g(3))(x)]$
- (32) a.  $\llbracket [\text{Dem } i_1 R_2]^{g, s_u}(\iota x [\text{Jana}(g(3))(x)]) \rrbracket$  is defined if the single Jana in  $g(3)$  is related by a contextually determined relation  $[ = g(2)]$  to some contextually determined entity  $[ = g(1)]$ . If defined, then  
 b.  $\llbracket [\text{Dem } i_1 R_2]^{g, s_u}(\iota x [\text{Jana}(g(3))(x)]) \rrbracket = \iota x [\text{Jana}(g(3))(x)]$

Let us now turn to the case DEM + predicative NP, representing the application of a demonstrative to a property-denoting expression (type  $\langle s, et \rangle$ ). Take example (33), repeated from (5).

- (33) Mirek je vlastně **ten právník**. DEM + PREDICATIVE NP  
 Mirek is PART DEM lawyer  
 a. ‘Mirek is the lawyer [that we met at the party yesterday].’  
 b. ‘Mirek is a lawyer [as I’ve just realized we’ve heard].’

The meaning of the pragmatic use of the demonstrative description *ten právník* is provided in (34). Notice that the system correctly derives the non-referential nature of the demonstrative description, which in turn affords a standard predicative interpretation of (33).

- (34) a.  $\llbracket [\text{DemP Dem } i_1 R_2 [\text{NP právník}_{\langle s, et \rangle}]] \rrbracket^{g, s_u}$  is defined if in the utterance situation  $s_u$ , some relevant utterance in previous common discourse  $[ = g(1)]$  is about  $[ = g(2)]$  the property lawyer. If defined, then  
 b.  $\llbracket [\text{DemP Dem } i_1 R_2 [\text{NP právník}_{\langle s, et \rangle}]] \rrbracket^{g, s_u} = \lambda s. \lambda x [\text{lawyer}'(s)(x)]$

Compare this to the canonical reading of the given demonstrative description. In this case, the demonstrative spells out both Dem and D and therefore conveys uniqueness, as indicated in (35). The meaning of the whole demonstrative description is in (36). It is a referential expression and the resulting interpretation of (33) corresponds to equation rather than true predication.

- (35) a.  $\llbracket [\text{DP D } s_3 [\text{NP právník}_{\langle s, et \rangle}]] \rrbracket^{g, s_u}$  is defined if there is a single lawyer in the resource situation  $[ = g(3)]$ . If defined, then  
 b.  $\llbracket [\text{DP D } s_3 [\text{NP právník}_{\langle s, et \rangle}]] \rrbracket^{g, s_u} = \iota x [\text{lawyer}'(g(3))(x)]$

- (36) a.  $[[\text{Dem } i_1 R_2]]^{g, su}(\iota x[\text{lawyer}'(g(3))(x)])$  is defined if  
the single lawyer in  $g(3)$  is related by a contextually determined relation [ $= g(2)$ ] to  
some contextually determined entity [ $= g(1)$ ]. If defined, then  
b.  $[[\text{Dem } i_1 R_2]]^{g, su}(\iota x[\text{lawyer}'(g(3))(x)]) = \iota x[\text{lawyer}'(g(3))(x)]$

In sum, I demonstrated how the two different readings of demonstrative descriptions in Czech can be modeled using the syntactic and semantic decomposition proposed in sections 3.1 and 3.2.2, combined with the assumption that deferred ostension is a concept that can be applied to discourse anaphora and with a different purpose.

### 3.3 An aside: The demonstrative determiner *tento*

The determiner *tento*, i.e. *ten* plus the postfix *-to* (see section 2.1) is the one that comes semantically closest to *ten*. As opposed to other modified demonstrative determiners in Czech, it can be used anaphorically, too (see Berger 1993 for an extensive discussion on *tento* and a comparison to *ten*). Nevertheless, it does not allow for pragmatic uses—neither anaphoric ones, nor affective ones. The present analysis offers a plausible account of this generalization. Suppose that the postfix *-to* spells out the D head, while *ten* spells out the Dem head. This simple assumption rules out pragmatic uses of *tento* altogether. A similar analysis was in fact proposed before—by Veselovská (1995: chapter 6)—and the present paper can be seen as a semantic argument for such an analysis. There is a caveat, however: according to the nanosyntactic spell-out principles I have adopted, *tento* should always be blocked by *ten* (joint spell-out of Dem+D takes precedence over individual spell-outs of Dem and D). I can think of two plausible ways of preventing this blocking: 1. It could be that *ten* in Czech is, in fact, lexically just Dem and that any potential iota-type-shifting is covert. 2. It could also be that *-to* spells out more than just D: if *-to* spells out D+X, then *ten* does not block its spell out (because *ten* cannot spell out Dem+D+X).

## 4 Extension: Affective demonstratives

The phenomenon of affective (also emotive) demonstratives seems relatively widespread; so far, it has been documented at least for Czech (Mathesius 1926), English (most recently Potts & Schwarz 2010), German (Potts & Schwarz 2010), and Japanese (Davis & Potts 2010). Since the Czech data have never been exposed to the field of formal linguistics, let me include a number of examples, complementing the English ones provided in the introduction. Some prototypical examples are provided in (37). Concerning (37-a), Mathesius (1926) notices that the affective character of demonstratives is intensified by the first-person possessive pronouns.

- (37) a. Ten náš tatínek nějak stárne. (Mathesius 1926:40)  
DEM our dad somehow gets.old  
‘Our dad is getting old [and we feel affectionate about him].’  
b. To sluníčko dnes hřeje. (Mathesius 1926:41)  
DEM sun.DIM today heats  
‘It’s hot in the sun today [and we find it pleasant].’

Mathesius further observes that the demonstrative and possessive determiners sometimes alternate with zero, giving rise to a scale of affectiveness—from the least affective (38-a) to the most affective (38-c).

- (38) a. Jen kdyby mne hlava nebolela. (Mathesius 1926:41)  
 only if me head NEG.hurt  
 b. Jen kdyby mne **ta** hlava nebolela.  
 only if me DEM head NEG.hurt  
 c. Jen kdyby mne **ta má** hlava nebolela.  
 only if me DEM my head NEG.hurt  
 ‘Only if I didn’t have a headache!’

I leave a precise semantic analysis of affective demonstratives for another occasion. Nevertheless, I would like to point out that the present proposal might offer a useful syntactico-semantic substrate for analyzing affective demonstratives. If we assume that they spell out Dem alone (rather than Dem+D), we derive the generalization that they do not shift the type of their NP complement. Consider the Czech examples above. All of them involve situationally unique definite NPs (‘dad’, ‘sun’, ‘head’), which are normally expressed by bare NPs in Czech (see, e.g., Běličová & Uhlířová 1996: chapter 3). The demonstrative therefore does not play the role of D. The Dem-based analysis also offers a new perspective of Lakoff’s (1974) conjecture that affective demonstratives are used in order to evoke hearer’s solidarity with the speaker’s own views. The basic instrument of Dem, due to Elbourne (2008), is the relational component. It does not seem entirely unlikely that the solidarity could be modeled using this relational component. It is possible, for instance, that the demonstrative establishes a relation between the NP denotation (referent) and some relevant common ground attitudes, i.e., attitudes held by all the interlocutors.

## 5 Summary and open issues

I proposed a new syntax-semantics for pragmatic uses of demonstratives. These are demonstratives which lack the properties of definite articles, particularly the uniqueness presupposition and the type-shifting capacity. On the syntactic side, the proposal builds on nanosyntactic principles (Starke 2009), which provide an elegant way of dealing with the apparent ambiguity of demonstratives. In particular, demonstratives either spell out two heads—Dem and D, a structure representing the canonical (definite-article-like) use of demonstratives, or only one head—Dem, representing the pragmatic use of demonstratives. On the semantic side, I argued that the contribution of demonstratives as viewed by Elbourne (2008) (and similarly so by Schwarz 2009 for the case of strong definite articles) should be distributed over the two heads: D hosts the definite-article semantics (uniqueness, type-shifting) and Dem hosts a relational component, establishing a relation between the denotation of the demonstrative description and some contextual entity.

With these instruments at hand, I provided a detailed analysis of anaphorically used pragmatic demonstratives in Czech (novel to the formal literature). I argued that they establish a relation between the NP denotation and an utterance in previous common discourse such that the utterance was about that NP denotation—a relation that relies on the concept of deferred ostension (see Elbourne 2008).

The proposal introduces a new method for analyzing pragmatic demonstratives in general. In section 4, I suggested how it could be extended to affective (emotive) demonstratives, a kind of pragmatic demonstratives attested cross-linguistically.

Many issues remain open, of course. One that particularly stands out is the issue of the relational component. Elbourne’s (2008) (or in fact Nunberg’s 1993) idea that demonstratives establish a relation between the denotation of the demonstrative description and something else is powerful and attractive in its flexibility. The present analysis might be taken as evidence that such flexibility is in fact exactly what is needed. On the other hand, by modeling the relation as an unrestricted

free variable, the approach clearly allows for many more kinds of relations than the ones attested so far (a relation of the DemP denotation to pretty much anything is a viable option). Further cross-linguistic investigations might reveal that languages do indeed make use of these various options. On the other hand, some quite severe restrictions are certainly needed to constrain the use of demonstratives within a single language. Take some examples: English does not seem to have anaphorically used pragmatic demonstratives. Affective demonstratives cannot be mechanically translated from one language to another. Where do these restrictions come from? Can they be derived from independent facts of individual languages or are we dealing with lexical idiosyncrasy? As far as I can tell, answers to these questions are not even at the horizon.
